Scientific comparison of a new in-ear sensor to measure oxygen saturation in the blood

Cooperation project of the company cosinuss and the Chair Exercise Biology (TUM)

Master thesis in sports science

Start: as soon as possible

Project description

In this pilot project, a new sensor (Cosinuss One^o) should be validated under real conditions to two established reference devices: Near Infrared Spectroscopy (NIRS) and finger clip.

NIRS will represent the cerebral SpO₂ and the finger clip will measure the peripheral SpO₂.

The validation should be done in a range of the SpO₂ starting at normal values of ~98% down to 70%.

Main research questions of part 1:

- What is the absolute difference of the three sensors?
- Do the sensors react in the same way to an artificial reduction of the SpO₂ or do we see a delay in between the sensors?
- Does physical activity influence the measurements of the three sensors?

If the new sensor works quite well, in a second project the sensor should be tested at COPD patients as well as control persons. This part 2 also would include the writing of an ethical approval.

Requirements

Interested in modern techniques.

Supervision

Dr. Martin Schönfelder, (Exercise Biology)

Dr. Fabian Stöcker (Prevention & Performance Labs)
